Abstract

The purpose of this study was to examine injuries attributed to muscle imbalance in sports with overhead movements. Available sources in the period between 2010 and 2020 that provide an overview of the occurrence of muscle imbalance and the risk of injuries in overhead sports were evaluated. A comprehensive search of relevant sources was conducted using Google Scholar, PubMed databases, and other databases, including Science Direct, Research Gate, Web of Science, and Psyc Info. Eleven articles met the criteria to be included in the systematic review. Muscle imbalance significantly impacted overhead athletes and was responsible for injuries of the shoulder, lower back, elbow, and wrist. Based on the findings of the review, further study on muscle imbalance should be carried out. More importantly, future research should investigate the muscle imbalance in the non-dominant side and identify relevant exercises that can reduce the imbalance and increase the stability and strength of the muscles on the non-dominant side. Researchers have identified muscle imbalance as a cause of the injuries, but detailed information on the prevalence of muscle imbalance and its impact on athletes remains lacking.

Keywords: dominant and non-dominant limbs, overhead sports, injuries, muscle imbalance

Introduction

Researchers have identified numerous overhead sports, including water polo (Lupo, Capranica, Cugliari, Gomez, & Tessitore, 2016), tennis (Correia, Oliveira, Vaz, Silva, & Pezarat-Correia, 2016; Trompeter, Fett, & Platen, 2017), rowing (Bahr et al., 2004), wrestling, and weightlifting (Baranto, Hellström, Cederlund, Nyman, & Swärd, 2009), golf and baseball (Lee, Tuite, & Rosas, 2010), gymnastics (Parikh, Case, Hogarth, & Abzug, 2020), badminton, basketball, handball (Kaplan, 2016), tracking, shooting, swimming, volleyball, karate, and futsal (Noormohammadpour et al., 2016). These sports usually require a player to apply a throwing technique or movement that involves shoulder and upper arm action above their head at one point or the other in the game. The athletes must also coordinate their movements in a kinetic chain from the feet to their hands (Kibler, 1998).

The execution of skills during competition and training requires the overhead athletes to perform multiple times within that period, whether it is acute or chronic. Hence the likelihood of developing a stronger side of the body is very evident. This is especially true for athletes or players in one-sided games, such as squash, badminton, and water polo. Unfortunately, this leads to muscle imbalance (Kraan et al., 2019), which has been linked to the occurrence of injuries as it substantially increases the risk due to the differences in strength, and this is directly correlated with the reduced performance of the athletes (Page, Frank, & Lardner, 2011).

Various training has been suggested to improve performance, but the mechanics applied by athletes, including shoulder elevation, increase the risk of injuries (Edmonds & Dengerink, 2014). The risks of overhead injuries are attributable to the distinct mechanics applied in the shoulder region,
including external rotation, abduction, and elevation. In addition, injuries may result from muscle imbalance, making the athletes prone to weakness in the shoulder and elbow (Noguchi, Demura, Takahashi, Demura, & Mori, 2014).

A well-structured rehabilitation programme is useful in the treatment of overhead sports injuries attributed to muscle imbalance. The biomechanics and frequencies of how the athletes use their body parts in the overhead sports determine injury patterns (Murray, Goudie, Petrigliano, & Robinson, 2013). For example, injuries to the upper limbs of athletes in overhead sports may vary depending on the specific aspects of that sport.

Most Common Injuries in Overhead Sports

Overhead athletes are susceptible to a significant number of injuries, with 18.3% and 21.4% upper extremity damages occurring during game and practice, respectively (Hootman, Dick, & Agel, 2007). Researchers argue that the majority of the injuries in overhead sports are a result of reduced training sessions. Koh and Dietz (2005) reported that a temporary reduction in sports activities increases the risks of injury when the players resume their schedule. However, some of the players maintain their training despite being in pain, thus increasing their risk of suffering injuries while attempting to improve performance. In addition, in overhead sports, athletes are expected to coordinate their movement at the shoulder, wrist, and elbow joints (Escamilla, Fleisig, Barrentine, Zheng, & Andrews, 1998; Fleisig et al., 1996). Therefore, during training or game competitions, the players tend to overuse the upper limbs, thus increasing the risk of joint disorders in the shoulder and elbow.

Studies have discovered injuries to the shoulder as a common occurrence among overhead sport athletes (Fahlstrom & Soderman, 2007). Shoulder pain is more common among badminton players. Shoulder pain is recognized as one of the most frequent injuries that affect female and male athletes. Nearly 30% of the overhead sports athletes suffer a shoulder injury in their careers (Laudehr & Sipes, 2009). Researchers also reported injury prevalence of approximately 34.7% to 66.7% in swimming and diving, respectively (Roos et al., 2015). Athletes are at risk of developing chronic conditions as they continue engaging in sports despite the pain. Studies have suggested that limited muscle strength increases the risk of shoulder injuries in overhead sports (Pennock et al., 2018; Atan, Yuceloglu Keskin, Camlidag, & Derebas, 2019). Moreover, the excessive range of motion applied to the shoulder also contributes to shoulder pathology among overhead athletes.

The increased popularity of overhead sports, such as baseball, tennis, and golf, has led to a rise in the number of people participating in sports activities (Wilk et al., 2009). Moreover, almost one in every four members of a family participates in these sports; therefore, hospitals and other health facilities are attending to more patients with elbow injuries (Wright, Hegedus, Tarara, Ray, & Dischiavi, 2018). Lee, Tuite and Rosas (2010) claimed that although injuries vary between adults and children, the risk factors are similar, including deconditioned state, suboptimal mechanics, and improper equipment. Equally, the biomechanical demands placed on the athlete’s elbow during upper extremity activities increase the risk of joint disorder (Zellner & May, 2013; Lam & Siow, 2012).

Parikh et al. (2020) also mentioned the so-called gymnast wrist as one of the injuries attributed to overhead sports. Excessive weight-bearing activities in the upper extremity result in a chronic wrist condition properly known as radial epiphysitis. Wrist injuries are commonly observed in gymnasts since they exert extreme pressure on the vulnerable region of the wrist. Moreover, tennis players are also susceptible to distinct wrist pathologies due to the stress fractures attributed to ulnar impaction and damages to the triangular fibrocartilage (Gil & Kakar, 2019). In addition, players may experience posterolateral labral tears, supraspinatus avulsions, and scapular dyskinesis. Thus, the majority of these athletes are susceptible to various injuries, including in the elbow, wrist, and shoulder (Putty, 2010), Low Back Pain (LBP), and because of the excessive force and stress applied during the activity of throwing or playing the overhead sports (Wilk et al., 2015).

Incidence of Muscle Imbalance

Overhead sports are closely related to injuries caused by a muscle imbalance in the elbow, wrist, shoulder, and lower back regions. In addition, muscle imbalance exposes athletes to an increased risk of joint disorders (Noguchi et al., 2014). Researchers have discovered that the alterations in muscle imbalance and flexibility are common among overhead athletes (Burkhart, Morgan, & Kibler, 2003), and hence proper balance to an athlete’s muscles is crucial for flexibility and stability in preventing potential injuries in the shoulder region. Athletes rely on muscles in distinct regions, such as the shoulder (Page et al., 2011), to enhance muscle performance during different motions and mobility in sports activities. However, muscle imbalances result in movement impairments due to changes in arthrokinematics, which may cause structural damages. Page (2011) claimed a deficit in the strength or flexibility in one muscle, such as an agonist, has to be compensated by another muscle, which in this case, is the antagonist muscle, thus leading to a dysfunction. Wang, Macfarlane and Cochrane (2000) also related muscle imbalance to isokinetic muscle strength, whereby muscular dysfunction, comfort, pain, and weaknesses in the shoulder regions are attributed to concentric and eccentric contractions on the dominant and non-dominant shoulders of athletes.

According to Page, Frank and Lardner (2011), muscle imbalance is attributable to weaknesses in different regions of the upper limb, including the lower and middle trapezius, infraspinatus, deltoid, serratus anterior, and when coupled with the tightness of levator scapula, upper trapezius, and pectorals, it increases the risk of structural damage for the athlete. Lin, Wu, Wang and Chen (2005) argued that increased activities in the trapezius muscle could result in substitution in scapular movement as compensation for the glenohumeral motion impairment. Athletes may be required to apply abnormal scapular motion, including increased upward rotation and excess elevation of the scapula (Challoumas, Artemiou, & Dimitrakakis, 2017). The players should understand that abnormal scapular motion causes imbalances in muscle activity. The imbalances can occur due to upward rotation and elevation of the scapula by the upper trapezius coupled with the contraction of the lower trapezius to maintain the equilibrium of the scapula (Wright et al., 2018).

Studies have also discovered a positive relationship between isokinetic evaluations and muscle imbalance. In sports in which athletes are expected to exercise overarm throwing, cases of imbalances in muscle strength have been identified in relation to isokinetic evaluations (Codine, 1997; Edouard, Damotte, Lance, Degache, & Calmels, 2013; Andrade et al., 2010). While exercising a throwing technique, athletes are expected to apply concentric and eccentric contractions (Olivier & Daussin, 2019). Although the concentric action influences the throwing velocity,
the eccentric contraction acts as a break limiting an increase in distraction force experienced in the upper limb (Sirota, Malanga, Eischen, & Laskowski, 1997). The use of a mixed ratio in internal and external rotators by concentric and eccentric actions increases the risk of shoulder imbalance, resulting in injuries.

Wang, Macfarlane and Cochrane (2000) argued that overhead sports such as volleyball, tennis, swimming, and javelin throwing require players to engage in repetitive forceful arm actions. The actions in these sports place an excessive eccentric load on the rotator cuff muscles of an athlete's shoulder, thus exposing them to injury. Therefore, an injured rotator cuff muscle is more likely to lose the capacity to maintain stability with the antagonist, and as a result of the imbalance in the shoulder region, an athlete is at increased risk of shoulder impingement. Moreover, Nekooei et al. (2019) argued that the majority of the overhead throwers face a similar problem, which involves an imbalance in the shoulder movement strength. Minimal internal or external glenohumeral rotations may cause injuries such as shoulder and LBP, and hence have a negative effect on the performance of athletes.

Researchers have identified differences in dominant and non-dominant sides of overhead athletes that are also responsible for potential injuries. The dominant shoulder of an overhead athlete is different from the non-dominant in terms of strength, morphology, muscular balance, and range of motion (Borsa, Laudner, & Sauers, 2008). Some of the sports activities may require the players to rotate the dominant arm at the maximum position while attempting to maintain a balance and level of accuracy. In volleyball, for instance, players try to produce high velocity and large forces on their arms by rotating the dominant shoulder; although they may achieve the expected results of accuracy, they end up being exposed to injuries attributed to muscular imbalance. In water polo, an overhead sport that exposes athletes to a number of injuries, especially to the shoulder region, players are expected to exhibit higher work in eccentric and concentric action and display high muscle endurance performance. Olivier and Daussin (2019) argued that the dominant shoulder of most water polo players tends to be stronger than their non-dominant shoulder. This imbalance increases the risk of injury to the shoulder region of an athlete participating in water polo.

Athletes are likely to suffer injuries attributed to muscle imbalance because of the different muscle forces applied in the dominant and non-dominant arm. The dominant arm applies muscle force nearly 10% greater than the non-dominant arm (Betchof, 1954; Gedela, Kirby, & Huhtala, 2008). Zuzgina and Wdowski (2019) considered the asymmetric nature of movements of an athlete's shoulder as a crucial cause of strength imbalances. Volleyball players are exposed to asymmetries between their dominant and non-dominant sides. However, other than the strength imbalances attributed to dominant and non-dominant shoulders, external and internal rotators play a crucial role in stabilizing the glenohumeral joint, and the failure to achieve a balance results in injuries.

The present systematic review looks into the occurrence of muscle imbalance and the risk of injuries linked to it, as well as the recommendation by the research.

**Methods**

The present study conducted a literature search for potential articles on databases such as PubMed, PsycInfo, ScienceDirect, and on the internet using Google Scholar. An additional search was carried out on the following databases ResearchGate and Web of Science. Keywords used to perform the search include muscle imbalance, overhead sports, dominant and non-dominant sides, and injuries. Database and internet searches centred on articles and papers within the period from 2010 to 2020. After identifying the potential papers and articles, screening of abstracts and full-text was carried out to select sources that would be assessed for eligibility using the "Strengthening the Reporting of Observational Studies in Epidemiology." Eligibility of the sources would help examine potential bias in the study. Relevant studies that passed the eligibility test were included in the review, as shown in Figures 1 and 2.

---

**FIGURE 1. Preferred reporting items for systematic reviews flow diagram of included studies**
Selection Criteria

All studies were first searched for on the internet using Google Scholar and different databases, including PubMed, PsycInfo, Web of Science, ResearchGate, and ScienceDirect. After that, the study screened the literature on the title and abstract using the following criteria: the target population (male and female overhead sport athletes, with overuse injury or pain of the shoulder, elbow, wrist, and lower back), design of the study (inclusive of all designs such as cross-sectional, systematic review, and case-control studies), and study outcomes (prevalence of injuries among overhead athletes associated with the incidence of muscle imbalance).

Results

The search strategy implemented in the review yielded 307 studies, and after deduplication, 157 studies were screened. The study tested 157 abstracts and excluded 120, leaving 43 of the sources for eligibility assessment. Only 11 out of the 43 assessed sources were selected for the systematic review (Figure 1). From Table 1 below, the eleven studies reported muscle imbalance as a key factor in overhead sports injuries.

Discussion

Findings indicated a significant correlation between muscle imbalance and damages such as lower back, shoulder, wrist, and elbow injury among overhead athletes. Muscle imbalance exposes athletes to an increased risk of joint disorders (Noguchi et al., 2014). Moreover, players of overhead sports are likely to suffer injuries attributed to muscle imbalance because of the different muscle forces applied in the dominant and non-dominant arms (Sung, Park, Kim, Kwon, & Lim, 2016). Scholars maintain that the dominant arm applies muscle force nearly 10% greater than the non-dominant arm (Betchol, 1954; Gedela et al., 2008). The dominant shoulder of most players tends to be stronger than their non-dominant shoulder. This imbalance increases the risk of injury to the shoulder region of an athlete participating in an overhead sport such as water polo (Olivier & Daussin, 2019). Another study identified an imbalance among golf athletes in the dextral arm muscles and sinistral arm muscles (Sung et al., 2016). Athletes who are unskilled in using the sinistral muscles depend on dextral muscles and are required to strengthen the dominant upper limb to maintain a balance between their arms (Sung et al., 2016).

Results of the review illustrated that muscle imbalance is attributable to weaknesses in different regions of the upper limb, including the lower and middle trapezius, infraspinatus, deltoideus, serratus anterior, and when coupled with the tightness of levator scapula, upper trapezius, and pectorals which increases the risk of structural damage for the athletes (Page et al., 2011). The study also found the asymmetric nature of movements of an athlete’s shoulder as a crucial cause of strength imbalances. Overhead sports, such as swimming and baseball, were found to expose athletes to functional impingement as a result of instability and muscle imbalance.

Additionally, the systematic review found that the external and internal rotators play a crucial role in stabilizing the glenohumeral joint, and a failure in achieving a balance results in injuries among overhead athletes. Muscle imbalance in the dominant and non-dominant sides of volleyball athletes exposed them to shoulder injuries. The results of the review added to existing research findings that confirm the association between muscle imbalance and overhead sports injuries. Wang, Macfarlane and Cochrane (2000) also related muscle imbalance to isokinetic muscle strength; musculoskeletal discomfort, pain, and weaknesses in the shoulder regions are attributed to concentric and eccentric contractions on the dominant and non-dominant shoulders of athletes.

Another study found that muscle imbalance associated with differences in the dominant and non-dominant arms to have a significant effect on baseball players. The study reported that the dominant arm was likely to have an abnormality on MRI that was 8.5 times more than the non-dominant arm, most of the baseball athletes are at risk of being diagnosed with rotator cuff injury, internal impingement lesions, and labral tears (Pennock et al., 2018).

In another study, the researchers discovered differences in trunk fatigue and the activation profile among tennis athletes, the players suffering from LBP were found to have minimal endurance time for their abdominal muscles. Furthermore, the extensor muscle activation procedure was also distinct among the players. The study reveals the importance of addressing problems with abdominal muscles and the activation of distinct trunk muscles, especially in lumbar stability activities, to help minimize the impact of muscle imbalance (Correia et al., 2016).

Noormohammadpour et al. (2016) also examine the prevalence of LBP in distinct overhead sports among female athletes. Research results involving 1,059 overhead athletes with a median age of 23.1 years indicate a 39.0% prevalence of LBP with badminton (42.4%), basketball (47.9%), and karate (44.0%). Lumbar kinematics tests during tennis serves also showed higher lateral flexion moments in LBP matches, which could be a possible injury mechanism (Fett, Trompeter & Platen, 2019).

Oleksy et al. (2018) discovered that differences in contralateral muscle fatigability might result in muscle imbalance and hence expose athletes to acute injury. However, a lack of differences in shoulder muscles of the dominant and non-dominant sides may not be a significant cause of pathological changes among volleyball players. The study concluded that asymmetric shoulder loading for volleyball athletes should not be assumed to be a potential risk factor for injuries to the shoulder region.

In another study that sought to evaluate the difference in dominant and non-dominant functioning of non-athletes and athletes’ arms, it was found that the dominant shoulder of handball and volleyball players had more scapular downward and upward rotation, especially in scapular rest (Hosseinimehr, Anbarian, Norasteh, Fardmal, & Khoosravi, 2015). In contrast, the study found no significant asymmetry in the dominant and non-dominant shoulders of non-athletes in distinct abduction angles when performing a scapulohumeral rhythm or upward scapular rotation. Also, from the review, the study found that muscle imbalance resulted from side-related adaptations of musculoskeletal and the different techniques used in frequency and pattern of the dominant and non-dominant arm.

Tonin et al. (2013) examined rotational mobility transitions associated with muscle imbalances from which the study identifies repetitive overhead movements, such as a decrease in the dominant external rotation, a higher deficit of the dominant eccentric external rotation peak torques, and a higher dominant rotator fatigue association with previous pain injury in the shoulders. Specific physiological shifts are interrelated (rotational mobility, symptoms of SICK scapula, and glenohumeral muscular imbalances). As a means of prevention and recovery for the at-risk athletes.

The study also revealed some of the crucial muscles that help overhead athletes avoid potential injuries, including the use of core muscles, rotator cuff muscle in strength training to enhance the strength of external rotation muscle (Coupe et al., 2014). The dextral arm muscles and sinistral arm muscles, and core muscles are essential for the golf and badminton players since they stabilize the backbone and maintain a player’s pelvis balance in swinging motion (Sung et al., 2016). Scholars have also identified other muscles crucial for athletes, such as the trapezius muscles and serratus anterior, which are important in maintaining a balance during upward rotation. Moreover, Lantz and McNamara (2003) identified additional muscles crucial among overhead sports players, including the middle trapezius, rhomboideus, and lower trapezius muscles, which help maintain the stability of scapula that may result in shoulder injury attributed to muscle imbalance.

The importance of muscle fatigue as a risk factor for shoulder injury in overhead athletes was highlighted by Andrade et al. (2016). A higher incidence of late-game injury than ear-
ly-game injury was documented and indicated that this fatigue might affect muscle strength balance and thus shoulder joint stabilization.

Conclusion
The overall findings of this study showed that overhead athletes are susceptible to shoulder, elbow, lower back, and wrist injuries attributed to muscle imbalances in either the dominant or non-dominant side. Athletes should engage in training and therapeutic programmes that help them learn techniques of avoiding potential injuries. Preventive strength training can help players balance and stabilize the rotator cuff muscle and minimize the chances of injuries. Furthermore, training allows players to learn proper throwing and pitching techniques, as well as restoring neuromuscular function to minimize the impact of muscle imbalance. Findings from the systematic review indicated that limited studies focus on the non-dominant side; thus, further research should focus on muscle imbalance in non-dominant upper limbs and its connection to overhead sport injuries and provide important programmes and exercise that can stabilize muscles in the non-dominant side.
